Overview

When the battery is at low voltage and the mains is stable, the inverter will switch to the mains priority mode. So which working mode can maximize the use of photovoltaic energy and meet customer requirements as much as possible?

What are the working modes of solar inverters?

Battery (solar) priority mode. How does it work to serve the power to the domestic load as priority instead of giving the power back to the grid?

Or on the other side: how the domestic load will get the power only from the inverter (if it's enough) and not from the grid (ie: 50% - 50%) if the "generators" are in parallel?

Until. Q: How the electricity generated by PV can be used to give priority to the user's load, instead of the PV power being sent to the grid, and the load is taken from the grid?

A: From the circuit principle, the current flows from the place where the voltage is high to the place where the voltage is. Modern off-grid inverters typically provide three main working modes: 1. This setting is ideal for regions with frequent power. For this inverter, the maximum reactive power injection/absorption is 0.6 x Apparent Power Rating (S rated). This inverter is also capable of "Q at Night", which can inject/absorb reactive power at night when no real power is being produced. What are we looking to accomplish and how will it all work together?

The next key factor to consider is.

First option: if the inverter is operating in what's called "Active Power Priority" mode, then active power (kW) takes precedence over kVAR. That means that the inverter will continue to operate
